ABSTRACT

The
Monthly Expense and Budget Analyzer
is a Java-based application designed to help
users manage their monthly budget and understand their spending habits. The program accepts the user's monthly budget and expense details, including category, description, and amount. It calculates the total expenses, average expense, highest individual expense, remaining budget or excess amount, and percentage of the budget used. Based on these calculations, it displays a budget status and warning messages to help users identify whether their spending is within the planned limit.
The application also provides category-wise expense analysis and identifies the category with the highest spending. It highlights expenses of
n1,000 or more and allows the expense
details to be saved to a text file and read again later. The program uses Java concepts such as variables, data types, conditional statements, loops, arrays, methods, classes, objects, collections, and exception handling. Input validation helps prevent invalid or non-positive expense amounts from being accepted.
Overall, the project demonstrates how basic programming concepts can be applied to a real-life financial task. It provides a simple way to summarize monthly spending, monitor budget usage, and make more informed decisions about expenses.
